

Stress & Strain during Mechanical Ventilation:

Clinical Application in ARDS

Manutham Manavathongchai, MD, MPA

- Stress = Transpulmonary pressure(T_p)
= P_{plat} – pleural pressure
- Strain = Δ lung volume/FRC = TV/FRC
- Stress = K x strain เมื่อ K = specific lung elastance (E_{Lspec})
- $T_p = E_{Lspec} \times TV/FRC$

Strain & TV

- Strain = $\Delta\text{lung volume}/\text{FRC} = \text{TV}/\text{FRC}$
- Heterogenous consolidation or atelectasis in ARDS: TV from each breath is delivered to the open alveoli.
- Alveoli
 - Open: low FRC; low TV
 - Recrutable: PEEP
 - Closed

Baby lung: alveolar overdistension

Cyclic atelectasis: collapse alveoli cause overdistension of adjacent alveoli
